

Figure 1 | Orthostatic hypotension is linked to cardiovascular disease risk and cardiac remodeling after spinal cord injury (SCI). **a**, Survey analysis of people with SCI identified a 2.77-fold increase in the risk of heart disease in people with cervical SCI and orthostatic hypotension compared to those without orthostatic hypotension. **b**, Cardiac magnetic resonance imaging was performed to assess cardiac anatomy and function after SCI. **c**, Shorter time to orthostatic hypotension correlated with altered cardiac magnetic resonance imaging-derived measures, including global extracellular volume, stroke volume, transmural time to peak longitudinal systolic strain, left ventricular end-diastolic volume, subepicardial minimum principal peak systolic strain rate and aortic valve total flow.
